The dataset offers detailed, up-to-date information on precious metals futures. Futures are financial contracts obligating the buyer to purchase, and the seller to sell a particular precious metal (such as gold, silver, platinum, etc.) at a predetermined future date and price.

Here' s the link to the dataset:

Precious metals have always played a pivotal role in economies worldwide, serving not only as currency, but also as a protection against economic ups and downs. This is the reason I found this topic quite interesting and chose it for my final project.

One of the things I've researched is this article: The Investopedia article on the history of gold prices details the significant highs and lows of gold prices over the years. Gold has historically been a safe-haven asset, seeing price increases during economic uncertainty and inflation. The article highlights key periods, such as the 1980 peak during high inflation and the 2011 peak amid global economic instability. It also covers the more recent trends, including the impact of the COVID-19 pandemic on gold prices. You can find more here: [Gold Price History: Highs and Lows](#)

- 6 Out-of-Sample Predictions
- 7 Comparison with ML Methods

Stock Open/Close Prices

We can first investigate the trend of the stock open and close prices over time.

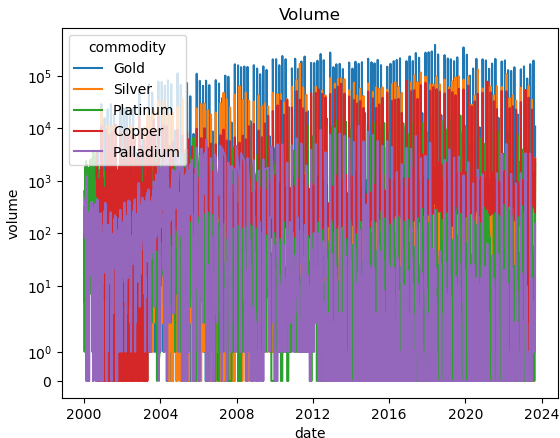

Observations: With the exception of Gold, the open/close prices for all the stocks have dips in their stock prices around the year 2008. We can speculate this is due to the 2008 financial crisis that occurred around that time.

- 6 Out-of-Sample Predictions
- 7 Comparison with ML Methods

Stock Volume

We can also investigate the trends of the stock volumes using a similar analysis.

We see that there is a lot of variability in the data. So, instead, something we could do is plot the moving average of the data.

Now we can investigate the trends of the percentage change over time:

 - Use of Dummy Variables
- 4 VAR / SVAR Model Building
- 5 Impulse Response Function Analysis
- 6 Out-of-Sample Predictions
- 7 Comparison with ML Methods

Stationary test is a vital step in analyzing time series, so let's go on and analyze the results obtained from the Stationary Test.
We observe that the p -values of all the tests are greater than 0.05, which signifies that the time series data have unit roots, and so are non-stationary.

- ① Introduction

 - Use of Dummy Variables
- ④ VAR / SVAR Model Building
- ⑤ Impulse Response Function Analysis
- ⑥ Out-of-Sample Predictions
- ⑦ Comparison with ML Methods

Our goal will be to predict the (open) stock prices of the different commodities in 2023 using the previous stock data. To do this, we will need to add some features to our dataset before passing it into modeling:

- We should add extra features that incorporate more information about the date variate; for example, the day, week, month, day of week, etc.
- We should add columns for the open, close, low and high prices for each commodity in our dataset.

Listing 1: Python code for adding datetime specific features

```
1 df["timestamp"] = df["date"].apply(lambda d: d.  
2 timestamp())  
3 df["day"] = df["date"].dt.day  
4 df["week"] = df["date"].dt.isocalendar().week  
5 df["month"] = df["date"].dt.month  
6 df["year"] = df["date"].dt.year  
7 df["day_of_week"] = df["date"].dt.dayofweek  
8  
9 df.sample(5)
```

To improve modeling, we should make the series stationary. To do this, we will:

- Apply a log transformation to the open stock price
- Compute the differences between the log open stock prices

Listing 2: Python code for a log transformation

```
1 df["log_open"] = np.log(df["open"])
2 for comm in commodities:
3     data = df.loc[df["commodity"] == comm, "log_open"]
4     df.loc[df["commodity"] == comm,
5            "diff_log_open"] = data.diff()
6     df.loc[(df["commodity"] == comm).idxmax(),
7            "diff_log_open"] = 0
8 df.head()
```

Now the data is stationary. The p-values are now extremely small (basically zero), which means this transformed variate is now stationary.

Optimal Lag Selection, Handling Insignificant Variables, Model Stability Check, Testing Residual Autocorrelation

```
# Fit the VAR model
model = VAR(commodity_close_prices_diff)
lag_selection = model.select_order(maxlags=15)

# Get the optimal lag length based on AIC
optimal_lag_aic = lag_selection.aic

# Fit the VAR model using the optimal lag length
var_model = model.fit(optimal_lag_aic)

# Display the summary of the VAR model
var_model_summary = var_model.summary()
print(var_model_summary)

# Check model stability
is_stable = var_model.is_stable()

# Calculate Durbin-Watson statistics for each equation
dw_stats = durbin_watson(var_model.resid)

# Perform Ljung-Box test for residual autocorrelation for each time series residuals
lb_test_results = {}
for col in var_model.resid.columns:
    lb_test_results[col] = acorr_ljungbox(var_model.resid[col], lags=[optimal_lag_aic], return_df=True)
```

Appendix: As we observed, gold prices are really sensitive to some unknown factors. The standard view is that S&P 500 and gold markets are negatively linked: when the stocks go up, gold prices decrease, and vice versa. This might be because gold is a safe haven, so traders sometimes may prefer gold to relatively risky stocks (S&P 500 - green line, Gold - yellow line).
